Check your site's error logs. It should display which files are corrupt. If nothing is shown in the error log, go through the includes subdirectories and remove all ver.php files. Then obtain the latest full install zip and upload all the ver.php files to all the various subdirectories of the includes directory. Be careful to get the correct files in each subdirectory. You should be able to upload but NOT overwrite files and that way it will only upload the missing ver.php files.
